13. ABSTRACT (Maximum 200 words)			
<p>A passive, colorimetric dosimeter badge was manufactured for NASA by GMD Systems. The badge consisted of two indicators: para-dimethylaminobenzaldehyde (PDAB) and vanillin. When exposed to hydrazine or monomethylhydrazine (MMH), the PDAB turns orange and the vanillin turns yellow. The intensity of the color is proportional to the concentration in the environment. A color wheel was also manufactured to evaluate the color and estimate the dose of hydrazine for each indicator. The laboratory investigations and the preliminary results of the field test indicate that the badge is qualitatively accurate with few interferences. The badges were exposed for sample times between 0.25 and 16 hours at different concentrations of hydrazine and MMH. The badges were evaluated for linearity, relative humidity effects, and interferences. The evaluation was conducted at the Naval Research Laboratory and Wiltech at the Kennedy Space Center. The badges responded with a measurable color change in each test. At low dose and short sample times, there was much scatter in the dose measured. The badges saturated, exceeding the darkest color on the color wheel after 8 TLV-hours. Relative humidity has little effect on the badge responses. Sunlight was an interferent for PDAB, turning it yellow. Tobacco smoke was an interferent for vanillin, turning it pink-purple.</p>

LABORATORY EVALUATION OF A COLORIMETRIC HYDRAZINE DOSIMETER

INTRODUCTION

The three hydrazines currently being used by the Department of Defense as hypergolic fuels are hydrazine, monomethylhydrazine (MMH), and unsymmetrical dimethylhydrazine (UDMH). The space shuttle program uses large quantities of hydrazine and MMH. In addition, substantial amounts of hydrazine are used by Titan missiles, satellites, and aircraft auxiliary-power units. While useful as propellents, the hydrazines impose health hazards to personnel who may come in contact with them. Hydrazine, MMH, and UDMH are considered potential carcinogens and threshold limit values (TLV) for exposure to their vapors have been established at 100, 200, and 500 ppb respectively by the American Conference of Governmental Industrial Hygienist (ACGIH) [1]. At higher concentrations there is added danger due to the explosive nature of the hydrazines. To minimize risk, monitoring of the employees and their work environment should be conducted to insure the presence of hydrazines remains below the defined levels. While instruments to monitor areas are commercially available, a small, reliable, real-time, passive device that can be worn by personnel is not.

Geo-Centers and Naval Research Laboratory (NRL) scientists invented a passive sampler for the determination of personnel exposure to MMH and hydrazine [2]. The sampler required laboratory evaluation. For real-time qualitative detection, a badge which incorporates vanillin as an indicator showed potential in laboratory evaluations at NRL. When exposed to a hydrazine, the coated substrate develops a yellow color. A patent for the vanillin indicator was issued in February 1990 [3].

GMD Systems, Inc. investigated several colorimetric systems for incorporation into a passive dosimeter through a Small Business Initiative Research Contract with NASA/Kennedy Space Center (KSC). One chemistry was identified by GMD Systems. This indicator, para-N,N-dimethylaminobenzaldehyde (PDAB), can also be used for real-time qualitative hydrazine detection. The PDAB coated dosimeter develops an orange-red color upon exposure to the hydrazines. NASA requested that the vanillin developed by Geo-Centers and NRL personnel be incorporated into the GMD prototype dosimeter badges. Geo-Centers and NRL personnel agreed to collaborate with GMD. An extensive laboratory test was designed to investigate the prototype badges. The color dosimeters were evaluated as dose indicators for MMH and hydrazine by NRL and by Wiltech at KSC.

The evaluation of the color badges was a joint effort between Wiltech and Boeing Aerospace Operations at the Kennedy Space Center, and NRI and Geo-Centers, Inc.

THEORY

The extreme reactivity of the hydrazines is responsible for a variety of technical problems encountered in performing ambient air monitoring. One approach that utilizes this reactivity is derivatization of the hydrazine to a species that is easier to analyze. There currently exists an ASTM analytical method that is based on the condensation of a hydrazine and an aldehyde, resulting in a product known as a hydrazone. The formation of a hydrazone is depicted in Figure 1. In the case of unsubstituted hydrazine (N_2H_4), two moles of aldehyde can react with one mole of hydrazine to form the azine. The mechanism involves the nucleophilic addition of the nitrogen base, followed by the elimination of water. This reaction is frequently acid catalyzed by protonation of the carbonyl. The ASTM method condenses the hydrazine with para-N,N-dimethylaminobenzaldehyde (PDAB), Figure 2. In an acidic solution, the absorbance of the protonated p-quinone structure is measured spectrophotometrically at 458 nm [4].

Figure 1. The condensation reaction of a carbonyl group with a hydrazine to form a hydrazone

Figure 2. Condensation reaction of PDAB with a hydrazine to form the protonated p-quinone structure

Vanillin (3-methoxy-4-hydroxybenzaldehyde) is also an excellent derivatization agent for hydrazine and MMH. Figure 3 shows the reaction of hydrazine and vanillin. The formation of the hydrazone is rapid. Vanillin does not need to be acidified to react with MMH, however, it does require acidification to form a colored species upon reaction with hydrazine. Reaction with UDMH does not form a colored species. This characteristic allows a wider pH range than with other aldehydes (such as the PDAB previously mentioned) when monitoring MMH. This has proven beneficial when investigating interferences, such as ammonia, that can alter the pH.

Figure 3. Condensation reaction of vanillin and hydrazine

The vanillin must be acidified to form a visual product upon reaction with hydrazine. Hydrochloric acid (HCl) was tested in this capacity, however, HCl was too volatile. Therefore, the use of citric, phosphoric and sulfuric acids were investigated. Phosphoric acid was the most suitable. We believe that non-acidified vanillin reacts with hydrazine to form the hydrazone. Upon acidification, the hydrazone turns yellow. This effect was used to make a badge sensitive to acid vapors [5].

EXPERIMENTAL

BADGE SYSTEM

Approximately 350 color badge systems were evaluated at NRL and 275 by Wiltech at the Kennedy Space Center. The badge designs incorporated vanillin and PDAB and were designed as dual spot units. Each unit was given a serial number and foil wrapped by the manufacturer. As a randomization procedure, all badges were scrambled by KSC personnel prior to distribution. The dosimeters were composed of two strips of filter paper coated with either indicator. These strips were sandwiched in a thin cardboard housing 7.3 cm by 4.4 cm in size. The housing face had two 1.25 cm diameter circles cut out for exposure of the coated paper. A tabbed section at the bottom of the badge provided a means of easily removing the protective cover over the indicator spots immediately prior to use. Figure 4 shows the badge. Badges with different color chemistries were designated as D12, D14, D13+D12, and D13. Later in the testing period, composite badges of D12+D14 were produced. Table I lists the indicators coated on each badge type. All badges with the exception of the D13+D12 badges and the later composite badges had a diffusion membrane over the indicator spot at the top of the badge. The membrane had little effect on color development. After three months of testing, the diffusion membrane was removed from all badges used in subsequent exposures at NRL. The membrane was not removed from the badges tested at Wiltech.

Back View of Badge

Figure 4. GMD Systems, Inc. Hydrazine Color Dosimeter

Table 1. Badge Types Evaluated

Badge Designation	Indicator	Testing Facility
D12	PDAB	NRL/Wiltech
D13	Vanillin/Citric acid	NRL
D14	Vanillin/Phosphoric acid	NRL/Wiltech
D13+D12	Vanillin/CA + PDAB	NRL/Wiltech
D12+D14	PDAB + Vanillin/Phos. Acid	NRL/Wiltech

GMD provided color wheels (badges dose indicators) with which to match the color development on the exposed dosimeters. During the course of testing, three different color wheels were used. The first consisted of nine shades of increasing intensity of yellow for vanillin (D13, D14) or red-orange for PDAB (D12). It was noted that some of the colors on the wheel were so close in shade there was difficulty in distinguishing between them. Another problem was that the low-dosage shades on the PDAB color wheel were much more pink than the badges exposed to MMH. The color mismatch made it difficult to read the badges well. New color wheels were produced with color intensities ranging from 1 to 5. The five colors on the new vanillin wheel were intended to be the same as the odd numbered colors on the original wheel. However, the number 4 color on the new wheel matched the number 8 color on the old wheel and the color of the number 5 dot on the new wheel was slightly more intense than the 9 color on the old wheel. The colors on the PDAB color wheel were altered slightly for more orange shades. This is more evident in the lower numbered color dots on the old new wheel. The intensities of the color dots on the new PDAB wheel were similar to the color intensities of the odd numbered colors on the old wheel. However, the number 4 color dot on the new wheel more closely matches 7.5 color on the old wheel. The number 5 color dot on the new PDAB wheel is slightly darker than the number 9 color on the old wheel. The new color wheel was used to evaluate the newer PDAB/vanillin (D12+D14) badges.

The shade of orange produced when PDAB reacts with hydrazine is different than that produced with MMH. Therefore, a different PDAB color wheel was designed for hydrazine exposures. The color spots on this wheel were orange.

TEST PLAN

The following tables outline the test plan for the dosimeter evaluation for MMH. Table 2a gives linearity test parameters, Table 2b, humidity parameters, and Table 2c lists interferents to be tested. Additional badges were sent to NRL for evaluation as hydrazine dosimeters under similar conditions. Each exposure was replicated. Some required doses were duplicated between NRL and Wiltech to insure no laboratory bias. The following tolerances applied to all controlled test parameters: MMH concentration (ppm), $\pm 20\%$; exposure time (hrs), $\pm 5\%$; relative humidity (%), $\pm 5\%$; and temperature (C), ± 2 .

To achieve the desired doses of MMH or hydrazine, the badges were exposed to various concentrations of the contaminant gas for different periods of time. Figure 5 shows the glass chamber in which the badges were exposed to MMH and hydrazine. The chamber was cylindrical with conical ends. The exhaust end was removable to allow insertion of the dosimeters. Teflon baffles placed at each end were used to induce laminar flow. The badges were hung vertically and back-to-back on a glass rod which was secured to the front and rear teflon baffles in the chamber. A flow of $5.0 \pm 10\%$ SLPM was specified for the evaluation. This corresponds to a velocity of 79 cm/min (2.6 ft/min).

The system used to generate MMH and hydrazine supplies concentrations from approximately 0.5 to 10 times the TLV for each compound. This system has been previously described in detail [6]. Diffusion tubes, housed in a constant temperature bath and continually purged with 100 ml/min of dry nitrogen, provide the hydrazine vapors. The desired concentration is obtained by adjusting the temperature of the bath, the size of the diffusion capillary, and/or the amount of dilution air. The concentration in the test chamber was independently verified using impinger collection and coulometric titration before and after each test. The coulometric titration procedure used to verify the concentrations of the dynamic test environment is described in detail in earlier reports [7].

The same type of glass chamber was used to expose the badges to the gaseous interferents that were tested at NRL. Badges were subjected to heat, cold, UV light and sunlight at Wiltech. Those badges exposed to heat and cold were placed in a convection oven (40°C) and freezer, respectively. To assess interference by UV light, badges were exposed to a UV lamp.

Immediately after each exposure ($T=0$), the color development on the dosimeters was judged by three people using the appropriate color wheel. Three people also judged the color on the badges one hour after exposure ($T=1$). Whenever possible, the same people who evaluated the badges at $T=0$ read them again at $T=1$. Although the colors on the color wheels were whole numbers (x), judges could choose a shade in between two colors (x.5), if necessary. The badges exposed to the interferents were evaluated both after exposure to MMH and to the interferent. The serial numbers, exposure conditions, and data obtained from each badge were recorded on log sheets (Appendices A and B).

FIELD TEST

The badges were field tested at Kennedy Space Center to investigate their performance in the field and to identify potential interferences. The badges were tested as area monitors and personal dosimeters. Individuals who wore the dosimeters were interviewed to determine their activities during the day. Eleven tests were conducted at different locations over a two month period. Three different location types were identified for testing: Expected Exposure, Unlikely Exposure, and Potential Exposure. Badges in the expected exposure area had a high probability of being exposed because hydrazine or MMH was being used or stored in that area. The unlikely exposure areas were used to test unusual interferences only, no hydrazine or MMH was ever used in those areas. The potential exposure areas included areas where hydrazines were used or stored at some time, but were clean during the test. These areas were selected to examine likely interferences. All of the tests and locations are given in Table 3.

Citric acid badges were used in conjunction with the colorimetric badges as a reference to independently monitor exposures. The performance of the citric acid badges was described in detail in an NRL Memorandum Report entitled "Field Evaluation of a Passive Sampling Device For Hydrazines in Ambient Air" [7]. Two badges were provided at each location. One badge was analyzed using coulometric titration [8]. The second badge was analyzed by a colorimetric method, phosphomolybdic acid, NIOSH approved method #S149 [9], or the badge was spiked and analyzed with the coulometric method. All of the badges were distributed and collected for analysis on a daily basis. For some tests, liquid impingers were also collected and analyzed by the ASTM para-dimethylaminobenzaldehyde colorimetric method.

RESULTS

DOSE RESPONSE RESULTS FOR MMH

All of the badges showed a large range in color development at doses less than 2.5 TLV-hours regardless of MMH concentration. At low sample times, some of the scatter is due to the experimental procedure. When the chamber is opened to insert the badges, the MMH atmosphere is disturbed. Thus, when the dosimeters are exposed to the gas for a short time, the atmosphere in the chamber may not stabilize during the time the badges are present.

Figures 6a and 6b are dose response graphs of PDAB (D12) badges without the diffusion membrane at T=0 and T=1, respectively. These badges show an increase in color development from T=0 to T=1. Although the time dependence is independent of dosage, the outlying data points at ≤ 5 TLV-hours show the greatest increase in color from T=0 to T=1. Because of this, the scatter in the outlying data points evident at T=0 is diminished by T=1 as the colors become more intense and approach saturation color. At 10 TLV-hours, the badges reached a saturation color of 9.5. Figures 6c and 6d are dose response graphs of the top color dot on PDAB (D12) badges that had the membrane. The outlying data points at < 5 TLV-hours noted on the badges without the membrane are not present here. Color saturation occurs by 16 TLV-hours at T=0. Due to the increase in color

Fig. 6c. MMH Dose Response Curve at T=0 for PDAB (D12) with Diffusion Membrane

Fig. 6d. MMH Dose Response Curve at T=1 for PDAB (D12) with Diffusion Membrane

development at T=1, badges exposed to 10 TLV-hours appear to reach saturation. At T=0, there is less scatter in the data taken from badges with a diffusion membrane than data from badges without a membrane. However, at T=1, the scatter for both types of badges is comparable.

Time dependence is evident for the vanillin/citric acid (D13) badges without the diffusion membrane. Figures 7a and 7b show the graphs for T=0 and T=1. At T=0, there is scatter at every dose. This is especially true for those exposures obtained at higher concentrations (1-6 ppm) and lower exposure times. These points increase in color significantly by T=1. They are no longer outlying points and have moved onto the response curve. The badges with the diffusion membranes over the top color dot Figures 7c and 7d give a smoother, more linear plot at T=0 than at T=1. There was a slight increase in color saturation between T=0 and T=1. The D13 badges that included the membrane in their design were only exposed to 0.1 and 0.2 ppm MMH. Those badges without the membrane were exposed to the entire range of concentrations stipulated in the test plan. If the data taken from concentrations of 0.4 and 1-6 ppm is disregarded for a direct comparison between the two types of badges, the scatter in both is comparable. The membrane has little effect on the color produced at any particular dose.

The vanillin/phosphoric acid (D14) badges without the diffusion membrane exhibit a slight color development time dependence. The outlying data points present at T=0 show the greatest increase in color by T=1. The curve looks smoother an hour after exposure. Several of the outlying points represent exposures to high MMH concentrations. Saturation occurs at 16 TLV-hours. Dose response plots of this data are found in Figures 8a and 8b. The badges with the membrane show little increase in color from T=0 to T=1. As shown in Figures 8c and 8d, there is much scatter at <2.5 TLV-hours as noted previously. Saturation occurs between 6 to 8 TLV-hours with a color of 9.5. The use of a diffusion membrane does not have an effect on the development of color. Both badges, with and without the membrane, develop comparable intensities of color.

In addition to each of the individual chemistry badges, a composite badge incorporating the vanillin and the PDAB (D13+D12) was designed. The same badge design was used incorporating one chemistry in each position. The diffusion membrane was not used. Dose response data for vanillin on the composite badges is shown in Figures 9a and 9b. The color development for vanillin increases from T=0 to T=1. With the exception of a few outlying data points, there is the same amount of scatter at both readings of the badge. Those points obtained at higher concentrations of the MMH show the greatest increase in color. Color saturation occurs at 10 TLV-hours. The vanillin color dot on the composite badges is slightly more sensitive to MMH than the noncomposite D13 badges.

Except for a few outlying points, the response curve is very smooth at T=0 and T=1 for the composite PDAB (Figures 9c and 9d). Almost all of the outliers have moved up into the linearity curve with increased color by T=1. Saturation occurs at 9 TLV-hours with a color of 9.5. The PDAB color dot on the composite badges is much more stable than the PDAB color dot on the noncomposite badges. The sensitivity to MMH is comparable for both badges. Incorporating the two chemistries on the same badge may permit each to influence the performance of the other.

The composite badges D12+D14, which were produced late in the test program, are PDAB and vanillin/phosphoric acid. PDAB was coated on the top of the dosimeter, while the

Fig. 9c. MMH Dose Response Curve at $T=0$ for PDAB (D12, D13+D12)

Fig. 9d. MMH Dose Response Curve at $T=1$ for PDAB (D12, D13+D12)

vanillin/phosphoric acid was coated on the bottom. These badges were tested at doses up to 15 TLV-hours with concentrations of MMH ranging from 0.15 ppm to 1.0 ppm. They were evaluated with the color wheel consisting of colors 1-5. There is an increase in color from T=0 to T=1 for both PDAB and vanillin. However, this time dependence is much pronounced in the PDAB badges. The scatter evident at T=0 is less so at T=1. Vanillin reached saturation by 15 TLV-hours with a color of 5.5. There are no data points between 2 and 15 TLV-hours; therefore, the exact saturation dose was not determined. The PDAB badges reach an average color of 5 by 15 TLV-hours. This data is plotted in Figures 10a-10d.

To compare the two color wheels designed for MMH, several of the composite badges D12+D14 were exposed to MMH and their color development was evaluated with both color wheels. Figures 11a and 11b represent dose response graphs of the PDAB spots on the badges. There was excellent correlation between the color wheels. The vanillin spots were evaluated as well. Figures 11c and 11d show the plots for vanillin. There is very good correlation between the two color wheels for vanillin. There appears to be the same amount of scatter for both vanillin and PDAB regardless of which color wheel is used for evaluation of the badges.

DOSE RESPONSE RESULTS FOR HYDRAZINE

Dose response tests with hydrazine were carried out at the TLV level (0.1 ppm) of hydrazine. Figures 12a-12d give the response data for the badges. PDAB (D12) shows a time dependence at doses less than 16 TLV-hours. Vanillin (D13) also shows a time dependence at the lower doses. Vanillin (D14) indicates a slight time dependence, while the composite badge (D13+D12) does not show this trend. The color change shows a good correlation with dose; however, there is not enough data to make conclusions on the precision or the saturation point.

Most of the data collected for exposure to hydrazine were obtained from the composite PDAB and vanillin/phosphoric acid (D12+D14) badges produced for use with the new color wheel. This data provides a more complete picture of the dose response of the badges for hydrazine. The data is represented in Figures 13a-13d. The saturation point at T=0 is between 3 to 3.5 TLV-hours for the PDAB. More data is needed to determine the saturation dosage for vanillin. Saturation color for the PDAB is 3.5. There is a slight time dependence in the PDAB data and a fair amount of scatter below one TLV-hour. The curve for PDAB shows slightly greater sensitivity for hydrazine than MMH at T=0. Vanillin, however, is more sensitive to MMH than hydrazine.

RELATIVE HUMIDITY RESULTS

When exposed to MMH at different relative humidities, badges D12, D13, and D14 were not affected in any consistent way. At <1.0 TLV-hours, the composite badge D13+D12 shows a slightly higher response at 70% RH for both D13 and D12. Limited testing was done with hydrazine at different humidities. When exposed to hydrazine at 70% RH and 40% RH, the composite badge D13+D12 and D14 displayed no effect in color development between the two humidities. At 2 TLV-hours, the D13 and D12 badges showed more intense color development with hydrazine humidified

to 70% RH than at 40%. However, more data points would be needed for statistical certainty. The data for RH effects on MMH is compiled in Tables 4a-4d. The responses are given by dose and humidity as well as the location of the spot on the badge (top or bottom).

For dosimeters D12, D13, D14, and the composite D13+D12, there is limited data on humidity effects for hydrazine. Table 5 gives the color intensity averages for the two humidities tested. There is not a consistent trend due to humidity for any of the badge types.

Composite badges D12+D14 were exposed to hydrazine at several humidities. Figures 14a-14d detail the relative humidity trends for the PDAB and vanillin sections of these badges. Vanillin is not affected by differing humidities. PDAB data shows lower color intensity for badges exposed to <10% RH at T=0. However, at T=1, the badges at <10% RH have increased in color intensity and no longer give lower results than the other humidities.

INTERFERENT RESPONSES

All interference tests involving heat, cold, UV light, and sunlight were carried out at Wiltech. Heating the badges was accomplished by placing them in a convection oven at 40°C. Badges exposed to cold temperatures were placed in a freezer. When a UV light source was used, badges were exposed to 254 nm or 350 nm wavelengths of light. Exposure to heat and cold lasted for 4 hours, UV light for 0.5 hour. The composite PDAB and vanillin/phosphoric acid (D12+D14) badges were used and evaluated with the 1-5 color wheel. The badges were exposed to heat, cold, and UV light both before and after exposure to MMH. The badges were exposed to sunlight prior to MMH exposure. Table 6 gives the color development of the badges exposed to MMH prior to these interferents. Table 7 shows color development for badges exposed to the interferents first, MMH second. The PDAB badges exposed to sunlight or a UV lamp were evaluated on the vanillin color wheel after interferent exposure as the color development was yellow.

Table 6 shows the interferent data in which the badges were exposed to MMH before the interferents. The colors of the badges were less intense than normal after exposure to MMH and prior to heat exposure. After subsequent exposure to heat, the increase in color brought the badges closer to the normal color intensity. Both PDAB and vanillin were affected by the addition of heat.

When the badges were exposed to heat for 2 hours before exposure to MMH, (Table 7) they showed a minimal color development. The average colors achieved after exposure to both heat and MMH, are less intense than the normal color development for 2.1 TLV-hours of MMH. The colors of both chemistries were less intense than the final colors achieved from exposure to MMH and then heat.

Exposure to cold temperatures after MMH exposure caused no significant changes in the color intensity of either badge. When the badges were exposed to MMH after 2 hours of cold temperatures, they behaved similarly to the heat interference. There was a minimal color development to the cold (0.5) and the badges achieved similar color intensities with the subsequent exposure to MMH. The final average colors were less intense than the colors normally achieved after

exposure to 2.1 TLV-hours of MMH for both PDAB and vanillin.

There was no significant change in color intensity from exposure to sunlight after MMH exposure. The average color for the PDAB badges after exposure to MMH was similar to the normal color intensity for 2.1 TLV-hours. The color of the vanillin was less intense than normal.

Exposure to a UV lamp source caused no significant change in color for either badge chemistries. When exposed to UV light initially, the badges developed a minimal color as they had with the heat and cold interferences. Exposure to UV light did not hinder subsequent color development in the presence of MMH. After exposure to MMH, both the PDAB and vanillin developed color of 3.2 intensity. This was normal color intensity for PDAB; slightly lower than normal for vanillin.

Several badges were exposed to sunlight alone during late summer (Table 8). They were tested in both horizontal and vertical positions for periods ranging from 0.25 to 2 hours. The vanillin badges showed no color development in either position. The PBAB badges developed 0.5 color within 0.25 hours and 1-2 color by 2 hours. These badges were evaluated on the vanillin color wheel as they developed a yellow color on exposure to sunlight.

Table 8. Sunlight Interferent Response

Badge Type	Badge Position	Exposure Time (hrs)				
		0.25	0.5	0.75	1.0	2.0

Van		0.0	0.0	0.0	0.0	0.0

Interferent tests with NO_2 , NH_3 , and freons were accomplished at NRL. The dosimeters were exposed to the interferents both before and after MMH. Exposure times for both the MMH and the interferents were one hour. Table 9a shows the data for NO_2 exposure after MMH exposure. NO_2 did not affect the badges after exposure to MMH. When exposed to NO_2 prior to MMH, the badges developed minimal color (0.5) after first exposure to the interferent as shown in Table 9b. NO_2 did not retard color development for subsequent exposure to MMH.

The PDAB badges were affected by exposure to NH_3 after MMH (Tables 10a and 10b). The color intensity of the badges increased after they were exposed to the interferent. The vanillin badges did not show a significant color change due to the interferent. As shown in Table 10b, both PDAB and vanillin showed a minimal increase in color of 0.5 when first exposed to NH_3 . Table 11a and 11b give freon exposure information. The PDAB showed a slight increase in color when exposed to MMH and then freons. The vanillin was not affected by exposure to freons before or after exposure to MMH.

A color change was observed on a few of the field tested badges. In most cases the color was very pale and in some cases the color was different than expected. Only one exposure was independently measured using the citric acid badge. This exposure occurred in the Witech Lab. Three citric acid badges showed a small hydrazine exposure. The vanillin proportion of the badge turned yellow on four of ten badges. Three of the badges corresponded to the positive exposures on the citric acid badges. The PDAB proportion of the badge showed an orange response in nine of the ten badges. These unverified responses have not been explained.

The PDAB portion of the badges that were field tested outside showed color development; this could indicate a sunlight interference. The PDAB spot turned yellow in several of the tests. In a few of the tests, badges outside did not develop color and badges inside turned pale yellow. The vanillin badge did not change color in the sun. The inconsistencies cannot be explained.

All of the vanillin badges in the break room (lounge) turned pale pink. The air in the break room contained much cigarette smoke. To evaluate cigarette smoke as an interferent, a badge was exposed to cigarette smoke in a jar. It also turned pink.

CONCLUSIONS

The dosimeters show a large amount of scatter in color development at low doses. Some of this scatter can be attributed to experimental procedure. The PDAB badges (D12) show the greatest amount of scatter. The use of a membrane does not significantly affect the performance of the badges. Color development shows a time dependence for all badge types tested. Therefore, the immediate color development of the badges should be viewed as a warning sign, while the later development of the color on the badges after removal from a contaminated area may be more accurate.

The composite badges (D13+D12) show an increased sensitivity and stability when compared to badges where the chemistries are used individually (D13, D12). The incorporation of two different chemistries on one badge may allow each to influence the performance of the other due to sublimation of the materials. Doses required to produce mid-range colors; that is, a color of 5 on the old wheel and a color of 3 on the new wheel, have been summarized in Table 12.

Relative humidity does not significantly affect the color development on any badge chemistry. The interferent tests indicate that heat is an interferent when badges are exposed to MMH first. Sunlight affects color development in the PDAB badges. The badges developed a yellow color that had to be evaluated with the vanillin color wheel. The PDAB badges were also affected by exposure to NH₃ after exposure to MMH. The vanillin badges were not significantly affected by the interferents tested. It was noted that vanillin is affected by tobacco smoke. A pink-purple color develops.

The yellow color development of the PDAB and the pink color response of the vanillin was observed in the field tests. The yellow responses of PDAB were not always consistent with the sunlight exposure. The expected color responses of orange for PDAB and yellow for vanillin were only observed in one location of the field test. The vanillin produced four positive results and all but one were independently verified. The PDAB badges produced six apparently false positive responses.

Table 12. Summary of Doses Required for Mid-Range Color

Badge Type	Gas	Diffusion Membrane	Dose (TLV-hrs)
